Abstract (Basic): US 5724523 A
     The system has at least one electronic data processing mechanism
   for executing programmed arithmetic and logical processes, and for
   storing data. There is at least one data input arrangement at a tax
   preparer site for inputting tax return data and credit card application
   data to a data processor. There is also a section in the data processor
   for dealing with the tax return data and creating associated electronic
   data files, and for processing secured credit card applications data to
   electronically **create** a deposit and loan **account** file. The file is
   used to **create** a collateral **account** for receipt of tax refund
   payments funding credit card issuance, with subsequent closing of the
   deposit and loan account.
     The data processor has a mechanism for processing the tax return
   files, and the deposit and loan account file. The tax return data is
   transmitted to a processor controlled by a tax collecting authority,
   for authorising electronic fund transfer to a **financial   institution**
   , into the deposit and loan account. Fund from the **account** are also
   authorised for transfer to the collateral **account** to fund secured
   credit card issue.
     ADVANTAGE - Provides data processing giving tax refund payment
   within 24-48 hours of time of filing tax return.

US 5689100 A   16 CIP of   US 95408960

Abstract (Basic): US 5689100 A
       The debit card system includes numerous debit cards, each assigned
    to one participant and having a unique account number corresponding to
    an award account of the participant. A **bank** filter processor accesses
    program data including data **identifying** the **authorized** unique
  account numbers of the participants, the **authorized** merchants and
    the balance in each participant's award account.
       The filter processor compares this program data to the following
    transaction data: the **initiating**   account number of the card
  initiating the transaction, the merchant identification data of the
    initiating merchant, and the data regarding the amount of the initiated
    transaction. The filter processor generates validating data for the
    transaction when the evaluated transaction data indicates that the
    transaction has been initiated by an **authorized** merchant using the
    unique **account** number of one of the participants having a sufficient
    balance in their award account to cover the transaction. Otherwise,
    invalidating data is generated.
       ADVANTAGE - Eliminates or minimises paperwork associated with
    transactions by which participants obtain rewards and track such
    earnings, redemption and accounts. Allows use of debit cards rather
    than credit cards.

Designated States (Regional): DE ES FR GB GR IT SE

Abstract (Basic): WO 9728636 A
        The method for carrying out services via interactive
telecommunication networks involves each player (1) establishing a
connection with the gambling station (6) and transmitting his
identification code, and also a desired game specification. The
telecommunication network is connected to a **bank** (3). Each player (1)
transmits his **bank account** number and/or his **authorisation** code
to the gambling station. The gambling station **establishes** a
connection to the bank. The gambling station returns an acceptance
signal to the player if the authorisation code is correct and the bank
account has coverage.
        The gambling station establishes a connection to the public
bookmaker (4,5) in question and collects relevant data on the game. The
gambling station makes the collected data available to the player via
the telecommunication network. The gambling station transmits
instructions to the player on how to handle his telecommunication
equipment to select the desired game combination and possibly correct
same. The player selects and transmits the desired game combinations to
the gambling station (6) according to the received instructions. The
gambling station transmits data related to the transaction to the bank
for acceptance. The gambling station transmits the accepted game
combination to the public bookmaker and a debit order to the bank. The
gambling station produces and takes care of the receipt for the
combination played and the debited amount and then send these pieces of
information to the player, so that a game procedure is fulfilled on a
binding basis.
        USE/ADVANTAGE - Allows players to participate in binding or
obligating way in games.

Abstract (Basic): EP 784282 A
      The method involves allowing a user to select (4) the **bank**
   account from which to make the withdrawal and a withdrawal amount, and
   establish a cryptographic secure session with a teller module (5). A
   request is sent to the teller module with the required transaction
   details to check the **account** and **verify** its validity and for
   sufficient funds. A **second** secure session is **established** with a
   money generator module (6).
      The teller module sends a create money request to the money
   generator with a note value, and the **bank** account is debited. The
   electronic representation of the money is generated in the requested
   note value and transferred to the teller module and thence to the
   transaction module.
      USE/ADVANTAGE - Relates to electronic monetary system for
   implementing electronic money payments as alternative to cheques, cash
   and credit and debit cards. Provides system of economic exchange that
   can be used by large organisations for commercial payments of any size,
   that does not have the limitations of **current** EFT systems.

Abstract (Basic): WO 9719414 A
        The network based payment system involves the user, an electronic
    bank and various merchants. Initially the user downloads software from
    the electronic **bank** system and this **establishes** an **account** . This
    includes an **identity** using features of the users machine, e.g.
    computer or modem serial number. The user can place money into the
    bank either by authorising a telecommunications supplier to deduct the
    money from the telephone account, or by supplying credit card details.
        The user can then contact suppliers of various goods of moderate
    value, e.g. $5-$20 and pay electronically by using the **identity** as
    validation of electronic money.
        ADVANTAGE - Allows creation of electronic funds on their computer
    which are subsequently billed by service provider. Prevents theft or
    misuse by providing transactions with associated identification
    indicia.

Abstract (Basic): WO 9531789 A
      The automated purchasing control method (94) involves receiving an
   authorisation request over the telephone line from a remote
   point-of-sale terminal (98) and processing the request using software
   having a database customised to a corporate user (70) to **establish**
   that company's hierarchical structure.
      Elements of the hierarchical structure are independently
   reconfigurable, so that a company can specify different hierarchical
   relationships in the software for authorisation, billing and reporting
   purposes. Different authorisation tests can be **established** for each
   position in a hierarchy, with a particular position being required to
   pass not only its own test, but the test of elements higher in the
   hierarchical tree.
      USE/ADVANTAGE - Automated purchasing control using credit cards in
   large company or corporation. Enables customisation for business
   customer. Allows company's expense and purchasing controls to automated
   and implemented without human intervention using purchasing or credit
   cards.

Abstract (Basic): WO 9512859 A
      The bill pay system includes a payment network (102) through which
    participating consumers (12) pay bills (30) to participating billers
    (14) according to preset rules (104). the participating customers (12)
    receive bills (3) from participating billers (14) (e.g paper/mail
    bills, e-mail notices, implied bills for automatic debits etc) which
    indicate an amount, and a unique biller ID number (120).
      To authorise a remittance, a consumer (12) transmits (2) to its
    participating **bank** (16) a bill pay order (122) indicating a payment
    date, a payment amount, the consumers account number with the biller
    (14), a source of funds (232) and the billers (14) ID number, either
    directly or by **reference** to static data containing the data elements.
    The system operates using an agreed set of protocols which include data
    exchange and message protocols as well as operating regulations which
    bind and direct the activities of the participants.
      USE/ADVANTAGE - Allows customer to direct their **bank** , agent of
    their **bank** , or non-**bank** bill pay service bureau to pay amounts owed
    to merchants, service providers and **other** billers who bill customers
    for amounts owed.

Abstract (Basic): WO 9512169 A
      The method for distributing currency involves using a magnetic
   stripe card (10) with an encoded card number including a **bank
   identification** number (14) and an **account** number (16) which is
   issued to a customer with a value selectable by the customer. A central
   card processor **establishes** a zero balance database including the card
   numbers, but with blank fields for the customer data and the value of
   the account.
      When a customer purchases a card, the sales agent (40) transmits to
   the central database computer (45) which fills in the blanks in the
   database (46), activating the account, and transmits an
   acknowledgement. The card can be immediately used in ATM (50) or **other**

remote terminals to acquire cash or purchase goods and services. The
customer inputs a PIN number which is provided with the card, or an
alternative PIN number selected by the customer.
    USE/ADVANTAGE - Dispensing currency, purchasing goods or services
to card holder in response to authorisation over data network. Provides
greater security than that offered by e.g signature on paper travellers
cheque.

WO 9412954	A1	E	20			
AU 9455566	A			Based on		WO 9412954
US 5539189	A		7			

Abstract (Basic): WO 9412954 A
    The system includes a central database (40). Financial information
of the institution relating to the holder of the bank or charge card
holder can be placed in the central database.
    Non-financial information received from a party other than the
institution and intended for the holder can be placed in the central
database. An authorisation device (43) reads the card authorisation
code and identifies the holder to the central database. The financial
information and advice concerning non-financial information can be
conveyed to the card holder.
    ADVANTAGE - Provides mechanism for communicating confidential
important messages over potentially large distance to specific person
at numerous locations.

Abstract (Basic): US 5193057 A
      The electronic data processing system includes electronic data
   processing programs provided for creating an electronic tax return that
   is filed with a tax collecting authority. At the same time as the
   electronic tax return is created, a loan application is processed to
    create an electronic deposit/loan **account** for the tax filer at an
   authorised credit institution. As early as the day after completion of
   the tax return and loan application, the tax filer receives initial
   refund payment from the loan account.
      The authorised credit institution electronically files the
   electronic tax return with the tax collecting authority which processes
   the return and transfers by electronic fund transfer the refund amount
   to the deposit/loan **account** at the **authorised** credit institution.
   Any refund in excess of the initial refund payment is then forwarded to
   the tax filer. Provision is also made for checking the credit
   worthiness of the tax filer.
      USE/ADVANTAGE - Authorisation and payment of refunds based on data
   supplied in electronically filed tax returns, reduces time from filing
   to receipt of refund to approx. single day.

Priority Applications (No Type Date): JP 8847559 A 19880302

Abstract (Basic): US 5012076 A
        The **bank** account consists of a storage area of account balance
    and transaction data and a **second** storage area for data indicative of
    a money amount shifted from the **first** account as cash data. In case
    of a money deposit, a data corresponding to a money amount to be
    deposited is subtracted from a cash data stored in an IC card and the
    data corresponding to the amount to be deposited is written into the
    first area. The data indicative of the drawn money amount stored in
    the **second** area is updated.
        If the intended transaction amount is less than the cash data the
    user enters his authorisation code and a data corresponding to the
    money amount to be transferred, or price of the commodity, is
    subtracted from the cash data stored in the card and the data
    corresponding to the transferred money amount is written into the
    first storage area. At this time, the data indicative of the drawn
    amount stored in the **second**   **account** is updated.
        ADVANTAGE - Enables **bank** transaction without overdrawing from
    account.
        Dwg.13/13

US 4851650	A		4			

Abstract (Basic): US 4851650 A
        The method of transaction processing comprises recording in a
    first store a sequence of parameters indicating a predetermined
    priority among a **first** series of accounts for processing a
    transaction. At least one corresponding parameter is read for an
    account from a **second** store. If more than one **account** is read from
    the **second** store, it is **compared** in an **account** selection unit
    with **account** parameters read from the **second** store storage and with
    the sequence of parameters in the **first** store.
        A transaction is processed through a highest priority **account**

determined by **identifying** a **first** parameter in the sequence of
parameters matching a parameter read from the **second** store. Each of
the parameters is selected to be that part of an **account** number
identifying a **financial** institution .
USE - Terminal unit for **bank** transaction processing.

DE 3809170	A		8			

Abstract (Basic): DE 3809170 A
     A manufacturer's code is recorded in the card and separately
transferred to an issuing station from a secured source. A validation
tester responds to the code recorded in the card and can receive an
entered code. It compares the received and recorded codes and indicates
that a card is valid when the codes coincide.
     The issuer's validity is also checked by comparing a stored code
with an entered code. If the card and issuer are both validated then
the information corresp. to them is transferred to the card which is
released for issue. The IC and contains a decoder which receives the
manufacturer's code in energised form.
     ADVANTAGE - Makes it practically impossible for lone operation of
issuing station to issue unauthorised IC cards.

Abstract (Basic): EP 107865 A
        A payment making system comprises an electronic cash register (10),
    a payment making terminal (30) and a personal **bank** card number
    keyboard (26). The electronic cash register (10) is capable of summing
    the goods or services purchased, reading and checking validity of the
    purchasers card when placed in the card reading slot (4). A print out
    of the transaction can be obtained from the printer (6) and details
    held in the cash registers memory.
        The payment making terminal (30) is capable of communicating with
    bank 's computer systems. The terminal (30) can accept the transaction
    details from the cash register (10), and the operator can by using the
    keyboard (21), card reader (23) and automatic dial key (22) contact the
    bank computer system. The purchaser are able to punch-in their own
    secret **bank** card number using the separate keyboard (26). The system
    automatically transfers the transaction cost from the purchasers
    account to credit the **account** of the **establishment** providing the
    service. The details of the transaction is displayed on the screen (24)
    and a receipt output from the printer (25).

Abstract (Basic): GB 2129181 A
        An electronic data processing centre is connected to the automatic
teller machine and has a memory for storing transaction item data
corresponding to various types of account numbers. The processing
centre is arranged to respond to a transaction processing request from
the automatic teller machine. Account number which is recorded on the
recording medium is transmitted to the processing centre and is read by
the automatic teller machine.
        A **second** transmitter reads out from the memory transaction, item
data corresponding to the account number data transmitted from the
first transmitter. The **second** transmitter also transmits the read
transmission item data to the automatic teller machine. A display
device. e.g. CRT selectively displays at the automatic teller machine,
the read transmission item data transmitted from the **second**
transmitter.

  19800204

Abstract (Basic): BE 886615 A
        Fraudulent use of **bank** and shop credit cards (9) is prevented by
printing on the cards a coded number which can only be issued after an
authorised machine operator has **identified** . The **account** and **other**
  coded numbers must also be entered.
        An operator at a keyboard (13) **initiates** an **identification**
number and an **account** number for a coding system (23) which also
requires **bank** **identity** data. This generates a data word which is
decoded for a **second** coder which requires the addition of a
particular secret identification number (21). The resultant output is
decoded for storage in computer files or on printed listings. A final
coder requires the addition of the card serial number before the
completed card can be issued.
Title Terms: PREVENT; FRAUD; CREDIT; CARD; ENTER; IDENTIFY; ACCOUNT; NUMBER
 ; DECODE; ISSUE

Priority Applications (No Type Date): US 75644559 A 19751229

Abstract (Basic): US 4023013 A
      In an on-line **banking** system including a central computer and
   remote terminals, the method is used for verifying that a holder of an
   identification card is **authorised** to complete a transaction. **Account**
    number data is machine read from the card, scrambled, and then
   compared to secret alphanumeric data, keyboard entered by the card
   holder at the terminal. The data is converted to a digital signal and
   converted into two portions.
      The **first** portion is **compared** to the scrambled **account** number
   data and the **second** portion of the keyboard-entered secret data is
   transmitted on-line to the central computer so it is impossible to
   determine the entire secret data for gaining unauthorized use of the
   terminal.
Title Terms: LINE; VERIFICATION; SYSTEM; **BANK** ; IDENTIFY; CARD; CONVERT;

ABSTRACT
PURPOSE: To execute interest rate changing processing profitable for a
depositor by comparing interests between a case depositing a time deposit
account deposited at an unchanged interest rate up to its expiration date
at the time of changing the interest rate of the time deposit, and a case
canceling the time deposit on-the way and redepositing it at a new interest
rate.

CONSTITUTION: A host system 3 finds out an interest rate to be applied to transaction data obtained by executing a time deposit new transaction by a **bank** terminal 1 and sent through a line 2 based upon a time deposit interest rate table 5, prepares time deposit account information and records the prepared information in a time deposit ledger file 4. At the time of changing the interest rate of the time deposit, the table 5 is updated, and in the case of an interest rate change increasing the interest rate as compared with the unupdated interest rate, the system 3 extracts a time deposit account deposited at the unchanged interest rate from the file 4, calculates respective interests obtained by a case depositing the deposit until its expiration date with a case canceling the deposit on the way on the interest changing date and redepositing it at the **new** interest rate each **account** , mutually **compares** the interests and executes processing for the case having higher interest amount.

JAPIO KEYWORD:R087 (PRECISION MACHINES -- Automatic **Banking**)

                          ABSTRACT
PURPOSE: To inquire about the information on a transfer destination only by a simple key selecting operation after putting a cash card into an ATM by storing the transfer information to be given to the ATM in a transfer information file and also registering a transfer requester number to the account information record to define a transfer requester.

CONSTITUTION: When a transfer requester puts a cash card into an ATM 10 and then inputs his password number, the automatic transfer information A is composed and a transfer destination collation processing means 32 is **started** . Thus the **account** - information record is read based on the contents of the cash card so that the account state and the wrong password number are checked. If the transfer is possible, the transfer requester number is acquired by the transfer requester and the transfer destination information is edited based on the contents of the transfer destination information record and outputted to the ATM 10. The transfer requester **refers** to the transfer destination information and inputs the automatic transfer information B through the ATM 10. Then, a transfer processing means 31 is started based on the information B and carries out the transfer processing. Thus, the automatic transfer processing is finished.

                            ABSTRACT
PURPOSE: To provide the check issue machine for managing the issue of a
check by judging whether the check can be issued or not by comparing the
bank account with the amount to be issued.
CONSTITUTION: Check issue amount data are inputted by an input means 9, the
new bank account is calculated from the inputted check issue amount
data by a remainder calculating means 11, a balance judging means 12 judges
whether the calculated new bank account is made minus or not, when
the new bank account is plus (when the bank account is not
broken,) it is confirmed whether the issue amount is proper or not, and
the check is printed by a printing means 71. When the judged result is
minus, an error message is displayed on a display means 8, a check issue
instruction is ignored, and the process returns again to the initial check
input mode without performing printing and balance updating.

                            ABSTRACT
PURPOSE: To provide a radio vending machine system which can solve such a
problem where the purchaser of a discharged commodity is not known and also
can quickly return a commodity when the relevant commodity is lost in a
system where plural purchasers purchase the commodities at a time through a
vending machine by means of each radio portable terminal.

CONSTITUTION: A vending machine 17, a center 1 and a radio base station 19
are connected to each other via a public network 24. The machine 17
 confirms the transfer of a bank account through the center 1 and
sells the commodities by the radio input of the commodities carried out by
a radio portable terminal 18. At the same time, a message including the
purchaser names is transmitted through a display part 6 and a speaker 10
out of the ID information received from the terminal 18. If a purchased
commodity is lost, the machine 17 judges from the ID information on the
terminal 18 that is written in the commodity by the input of the commodity
carried out by the finder of the lost commodity. Then the machine 17 sends
a voice message to the terminal 18 of the purchaser to notify that the lost
commodity is found.

                27, 1994 (19940427)

ABSTRACT
PURPOSE: To shorten memory check time at a multiprocessor system.

CONSTITUTION: When a system is started, CPU 11 and CPU 12 check local
memories 14 and 15 which they themselves have, **refer** to an allocation
table in ROM 18 and recognize **banks** which they themselves share among a
common memory 16. Thus, CPU 11 checks a **bank** 16-1, and CPU 12 **banks**
 16-2 and 16-3. In such a case, the respective **banks** are in the same size
and CPU 12 has processing speed twice as much as that of CPU 11. Thus, time
which both CPU require for **checking**   the memories becomes equal, and
 starting processing time as the whole system is shortened.

ABSTRACT
PURPOSE: To save a customer the trouble of going to a **bank** for the
purpose of cancelling his account or depositing money again except for a
special demand and to omit the processing of account cancel and redeposit
on the **bank** side by automatically determining a new interest at the time
of expiration of a term of the deposit account.

CONSTITUTION: This system is provided with a first storage means 9a where
the interest for each deposit **account** is stored, a **second** storage means
8b where an interest calculation formula preliminarily determined for each
deposit account is stored, and a third storage means 9c where **reference**

interest information independently determined by a **banking** organ is stored; and at the time of expiration of the term of the deposit **account** , a **new** interest is determined in accordance with **reference** interest information stored in the third storage means 9c and the interest calculation formula which is stored in the second storage means 9b and is preliminarily determined for each account, and the interest for each account stored in the first storage means 9a is rewritten with the new determined interest to automatically update the accout whose term expires.

ABSTRACT
PURPOSE: To obtain a device not requiring a magnetic card and a password number by providing a means to convert a voice inputted by an operator to a digital signal, and a means to confirm the operator by analyzing the digital signal.

CONSTITUTION: When the operator inputs the voice to a microphone 2 in an automatic cash transaction device 1, a voice transaction signal is introduced to a host device 9 via a voice input processing part 3, a control part 4, and a communication processing part 5. The host device 9 confirms the operator by collating voice feature data in the voice transaction signal with voice feature data stored in advance, and finds out **account** information **established** by the above operator. Thence, the validity of a transaction content can be **confirmed** by the **account** information and the transaction data deduced from the above, and instruction information is sent out to the control part 4 via the communication processing part 5. The control part 4 issues the instruction of input/output of money to an input/output part 8 according to return information.

APPLICANT(s):   OKI ELECTRIC IND CO LTD [000029] (A Japanese Company or
                 Corporation), JP (Japan)
APPL. NO.:   01-265098 [JP 89265098]
FILED: October 13, 1989 (19891013)

ABSTRACT

PURPOSE: To automatically **open** a **new** **account** or cancel the **account**
via a machine by **verifying** the person himself/herself based on a photo
of his/her face photographed by a video camera and that attached to an
identification card.

CONSTITUTION: A comparison means 6 compares an image pattern of the face of
a customer photographed by a video camera 4 with that of a photo of the
customer's face read by a document reader 2. When the coincidence is
obtained between both image patterns, the person himself/herself is
confirmed . Thus, a **new** **account** of the customer is **opened** or
cancelled. In such a constitution, a **new** **account** is automatically
opened or cancelled by a machine with no manual operation required. Then
the business tasks are rationalized at the window.

AUTOMATIC TRANSACTION APPARATUS

ABSTRACT

PURPOSE: To shorten a transaction time by constituting the title apparatus
of the **first** means reading account data, a means judging the presence
range of the character and figure of an **account** **confirming** medium, the
second means reading the character and figure of the **account**
confirming medium and a means printing the character and figure.

CONSTITUTION: A card C is inserted in a card insertion port 6. The
transaction account number and password number of the card C are read by a
magnetic head 34 and the results are outputted to a control part 57. The
control part 57 judges the transactions in a loan account on the basis of
the transaction account number read from a magnetic stripe Cb and judges
that an embossed part E is positioned on an upper side. An emboss reading
control circuit 55 reads only the range indicated by the control part 57 to
output the result to the control part 57 while the control part 57 stores
said result in an internal memory. A customer inputs a password number and
a main control part 11 collates the inputted password number with the
password number read from the magnetic stripe Cb and judges that
transactions are possible when coincidence is judged to input a payment
amount. A printing head 41 prints the transaction results and the content
of the embossed part E of the card C on journal paper

                April 26, 1991 (19910426)

ABSTRACT
PURPOSE: To perform printing in the same direction independent of different
transaction items by constituting the title apparatus of the first means
reading account data, a means judging the direction of the character and
figure of an account confirming medium, the second means reading the
character and figure and a means printing the character and figure in the
judged direction.

CONSTITUTION: A card C is inserted in a card insertion port 6. The
transaction account number and password number of the magnetic stripe Ca of
the card C are read by a magnetic head 34 and the results are outputted to
a control part 57. The control part 57 judges the transactions in a loan
account on the basis of the read transaction account number to judge that
the characters of an embossed part E are inverted. An emboss reading
control circuit 55 reads the characters of the embossed parts E to output
the result to the control part 57 which in turn stores said result in an
internal memory. A customer inputs his password number and a main control
part 11 collates the inputted password number with the password number read
from a magnetic strip Cb and, when coincidence is judged, said control part
11 judges that transactions are possible to input a payment amount. A
printing head 41 prints the transaction result and the content of the
embossed part E in the same direction independent of transaction items

ABSTRACT

PURPOSE: To make manual operation unnecessary for the registration of a
personal identification number by providing a personal identification
number temporarily storing means, a **comparing** .collating means, an
 account   opening means, a card stocker and a means to write information
for a card in a cash card.

CONSTITUTION: A customer inputs the personal identification number by using
a personal identification number inputting means 401 installed at a display
4. A processor 1 stores temporarily this inputted personal identification
number in the personal identification number temporarily storing means 501
installed at a memory 5. Next, it displays indication to urge re-input, and
the customer re-inputs again the same number as the personal identification
number inputted before by using the means 401. The comparing means 101
compares and collates this re-inputted number with the number stored in the
means 501. This is for preventing the personal identification number
different from the thought of the customer from being registered. In the
case of coincidence, data processing for **opening** a **new   account** is
executed by the **account   opening** means 102.

AUTOMATIC TELLER MACHINE

ABSTRACT

PURPOSE: To eliminate a recording medium such as a **banknote** dedicated to
recording transaction information by using a portable storing medium as a
transaction medium and storing the transaction information in the storage
circuit of the portable storing medium.

CONSTITUTION: An account balance that a card reader 12 reads out of the
portable storing medium is transmitted to a main control part 11. It
 compares the transmitted **account** balance with a paid account held in a
RAM, judges whether the paid account lies within a payable range or not,
starts outputting cash with the aid of a money I/O unit 14, and pays out
cash corresponding to the inputted paid account. Then the main control part
11 stores the **current** transaction information in the storage circuit of
the portable information storing medium through a card processor 12, and a
 new   account as well.

AUTOMATIC ACCOUNTS INFORMATION MULTI-JOURNALIZING METHOD BASED UPON PATTERN

CODE

ABSTRACT

PURPOSE: To efficiently and easily enable any person to execute precise
accounts processing by previously registering a concrete journalizing
pattern in a file and referring a journalizing pattern coincident with
the pattern of journalizing data.

CONSTITUTION: The concrete journalizing pattern is previously formed on the
basis of a forecasted journalizing pattern and a direct pattern name and a
code No. appropriate to data to be journalized are registered in a register
card 1 so that the formed pattern can be easily extracted. The journalizing
pattern is constituted by displaying all forecasted deptor and creditor
items belonging to the pattern and their item code Nos. and entering the
amount while properly selecting a necessary item in accordance with the
accounts data. When the accounts data are generated, the registered
journalizing pattern having the same pattern as that of the accounts data
is referred to form a new journalized accounts data directly.

AUTHORIZING DEVICE FOR INDIVIDUAL CARD

ABSTRACT

PURPOSE: To authorize an electronic card on which plural pieces of
 individual authorization information are stored securely by reading one
optionally specified pieces of individual authorization information and
deciding whether the information is approved or not.

CONSTITUTION: The electronic card is loaded in an individual card
 authorizing device and a password number is inputted on its keyboard and
sent to the electronic card, and the number is compared with the password
number set in PIN memory, thereby displaying an OK signal when they
coincide with each other . Then, a number corresponding to a desired
credit card company is inputted and sent to the electronic card to read the
company code corresponding to the number out of an individual
 authorization information memory to check whether the company code is

registered in an associative card company memory or not. When it is judged
that the company is registered, the account number of the company is read
out of the electronic card and compared with the storage contents of an
ineffective card account number list memory; when it is judged that the
account number is not an ineffective **account** number, a normal transaction
is **started** .

TERMINAL CONTROL SYSTEM

ABSTRACT
PURPOSE: To eliminate the necessities of an operation for the zero
proofing, by matching and collating a payable account with a payment amount
breakdown data and outputting the payment amount type breakdown data with
the payment designation after the reply concerning the ''able to be paid''
from a central device.

CONSTITUTION: When the payment demand account is inputted from an operation
part 1, it is displayed at a display part 2, and the payment demand account
data is stored in a payable account preserving register 5. The ''able to be
paid'' and ''unable to be paid'' data is returned from the central device
7. Thereby, the control part 3 displays the error at the display part 2 at
the time of the ''unable to be paid'' data. At the time of the ''able to be
paid'' data, the portion checks whether or not the payable amount data is
added in the data. When the data is added, the payable account data is
stored to the payable **account** preserving register 5. The proof
 establishment is displayed by **comparing** the **account** and the **account**
of an amount type breakdown register 6.
